Questionnaire Design

Experiment Validity

Workshop

- In HCI research, the most accepted method is **experimental method**.
- **Golden rule** is 70% quantitative (verification of effects) and 30% qualitative (tell us why)
- In experimental research, **comparative evaluation** is often done, where **proposed solution** is pit against (1) **state-of-the art** technique and (2) **baseline** technique.
 - Baseline allows comparison of results with past studies. State-of-art allows comparison of proposed solution against the “best”

Questionnaire Design

Experiment Validity

Workshop

- IV are variables we **manipulate**. Also called **factor**. What should be our IV?
- Our first IV is the **menu type** which has two **levels**: pie menu and linear menu
- To increase our research generalizability, we can further add more IV, for example:
 - Second IV: **menu breadth** with 3 levels: 4, 8, 12
 - Third IV: **menu depth** with 3 levels: 1, 2, 3
 - Fourth IV: **usage** with 2 levels: mobile and stationary

Thus our work is a **2 x 3 x 3 x 2 factorial design**

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

- Levels are sometimes called **conditions**.
- Other common IV such as feedback modality, selection technique, and so on...It is **recommended to choose between 2-3 IVs** for any experiment.
- Having too many IVs are impossible to interpret. For example, a design with one IV has *main effect* but no *interaction effect*. Two IV has two *main effects* and one *interaction effect*. Three IVs - there will be seven effects!

Independent variables	Effects					Total
	Main	2-way	3-way	4-way	5-way	
1	1	-	-	-	-	1
2	2	1	-	-	-	3
3	3	3	1	-	-	7
4	4	6	3	1	-	14
5	5	10	6	3	1	25

Questionnaire Design

Experiment Validity

Workshop

Dependent variable (DV) is **what you measure** - they **depend** on the factors. So what's our DV?

- For our case study:
 - **Speed**: measured as completion time
 - **Accuracy**: measured as error rate
 - **Learning**: measured speed and accuracy improvements change over time
- Good DVs are usually **numbers in continuous scale**
- Recommended to have **2-4 DVs**. Why not too little or too much?

Dependent Variables

Confounding Variables

Within- and between-subjects

Order Effects

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

- In HCI, the most common DV is **speed** (reported in task completion time) and **accuracy** (reported in error rate)
- Others include preparation time, action time, throughput, gaze shifts, mouse-to-keyboard hand transitions, preses of BACKSPACE, target re-entries, retries, key actions, gaze shifts
- Also some creative: count of negative facial expressions, number of times users shift their gaze from on-screen keyboard to the typed text.
- When reporting, it is important to see the **common units used in earlier work**, so your work can be compared

Questionnaire Design

Experiment Validity

Workshop

- **Within-subjects** uses **less** participants, prone to **practice effect** and thus require more **testing**. Usually preferred.
- **Between-subjects** uses **more** participants, prone to **effect of individual differences** and thus require effort to **balance** all groups. However, certain experiments require between-subject such as drug experiment or gender experiment
- **Mixed-design** uses both within-subject and between-subject in one design. For example, the experiment has two factors: block is within-subjects with perhaps 10 levels (block 1, block 2...) and handedness is between-subjects with two levels (left, right)

Random Variables

Confounding
Variables

Within- and
between-subjects

Order Effects

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

In our study, within-subject is the clear choice. Choosing between-subject will **require lots of participants** in order to balance out the effect of individual differences. The more factors (subsequently the conditions), the more participants we are required which is costly. On the other hand, within-subject is prone to **practice/learning effect** which can be easily fixed by administering **block design**.

Within- and between-subjects

Order Effects

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

- Order of conditions may affect the results, e.g., **fatigue**, **learning effects**. Thus it is necessary to *counterbalance* the order of conditions across participants
- **Latin Square** is a common method for counterbalancing.

Confounding Variables

Within- and between-subjects

Order Effects

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

- A deficiency in Latin squares of order 3 and higher is that conditions precede and follow other conditions an **unequal** number of times. In the 4 x 4 Latin square, for example, B follows A three times, but A follows B only once
- **Balanced Latin-square** addresses this. The top row has the sequence A, B, n , C, $n-1$, D, $n-2$, etc. For following rows, simply add 1

(a)

A	B	D	C
B	C	A	D
C	D	B	A
D	A	C	B

(b)

A	B	F	C	E	D
B	C	A	D	F	E
C	D	B	E	A	F
D	E	C	F	B	A
E	F	D	A	C	B
F	A	E	B	D	C

Control Variables

Random Variables

Confounding Variables

Within- and between-subjects

Order Effects

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

- The one drawback of balanced Latin squares is that it only works for **even** number of test conditions
- One may draw out all possible combinations ($n!$) (**full-counter balancing**) but would require more participants (here we could recruit 18 participants, each set with 3 participants).

Variables

Within- and
between-subjects

Order Effects

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

- Another way to address this imbalance is to simply **randomize** the order of conditions. This is suitable when the task is **very brief**, there are many **repetitions** of the task, and there are **many test conditions**.
- Last, it is recommended to look at **earlier works**, to see the common acceptable counterbalancing method

Order Effects - Skill Transfer

Questionnaire Design

Experiment Validity

Workshop

- Consider an IV with two levels (A:keyboard, and B:keyboard with word prediction). Participants who do A then B were found to perform better than B then A, because participants are allowed to learn the easier method first in A (Koester and Levine, 1994a), this is called **skill transfer**
- In this kind of case, it is recommended to use **between-subject design**

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

- In our case, we have four IVs - menu type (MT) (2), breadth (B) (3), depth (D) (3), and usage (U) (2)
- We can safely assume that there is no skill transfer
- **Menu type** - full counter-balanced - is only two level
- **Usage** - full counter-balanced
- **Breadth and width** - randomization or sequential
- Thus, we will have four conditions - MT1U1, MT1U2, MT2U1, and MT2U2. We will denote them as A, B, C, D. We can use balanced latin square which will give four sets: ABDC, BCAD, CDBA, DACB. Thus our number of participants will be multiples of 4; 16 and 20 are good numbers.

Designing HCI Experiments

Research Question

Participants

Independent Variable

Dependent Variable

Control Variables

Random Variables

Confounding Variables

Within- and between-subjects

Order Effects

Task and Procedure

Questionnaire Design

Experiment Validity

Workshop

- This will be a design with 16 body positions \times 3 postures \times 4 durations \times 3 trials = 576 trials
- Since each trial takes around 1s with 2.5s in between, the total time is $3.5s \times 576 - 2.5s = 2013.5s / 60 = 33.558$ mins - this is fair amount of time when counting time for filling questionnaires
- The **order** of body positions and stimulus duration were randomized but each body position will receive exactly 3 trials for each stimulus duration. After one posture is done, we swap to another posture. The order of posture is done using Latin-square
- The **speed of walking** must be controlled across participants (1.25m/s). The fast walking was using 4.5m/s
- **Participants** could be blind people or teenagers depending on the target audience. 15 should be nice numbers since it's the 3s multiple of the Latin-square
- **Place of environment** - could be another IV but would require another study
- After each posture, participants rated their perception of the vibration for each body position, with 1 - most difficult to perceive and 7 as easiest to perceive

Experiment Validity

Workshop

Figure: Source: Zheng et al. CHI 2018

- **Problem Statement:** We have proposed a gesture menu used in mobile phones - How does the newly proposed gesture menu compared to linear menu (baseline)?
- **Independent variables:** Input method (linear menu vs. gesture menu), Depth (1, 2, 3), Execution (guided, recall)
- **Dependent variables:** Time and error rates
- **Design the rest of the experiment,** including the task and procedure, the participants, the order effects, number of trials and blocks, and last, calculate the total time of the experiment

- **Depth** is one of the challenge. In D1, there are 8 possible gestures, D2 - 64 gestures, D3 - 512 gestures. To test all depths, it is possible to test completely D1 and 2 gestures, not but D3. And due to time, we definitely cannot test more than D4 and so on. For D3, we may test another 64 gestures randomizing from the sample of 512 gestures, depending on the experimental time. Since depth is an increasing complexity, the order will be strictly D1 - 2 - 3
- Another issue is the **recall** and **guided**. Obviously we should test guided before recall since there is nothing to recall.
- **Input method** can be easily fully counterbalanced
- For the **number of trials**, this needs to be prior tested before knowing how many repetitions before participants start to be good at using our menu. We found 4 trials are adequate
- This could be a design with 2 input methods \times 136 gestures \times 2 execution \times 4 trials = 2176 trials
- Since each trial takes around 1s with 1s in between, the total time is $2s \times 2176 \text{ trials} - 2s = 4350s / 60 = 72.5 \text{ mins}$ - this amount of time could be too much for participants. Thus you may want to do only 32 gestures for depth 3. Try recalculate. How much total time?
